#### FOREWORD

This is the second of three volumes describing the Performance Analyses and Design Synthesis (PADS) computer program. This volume is devoted to programming and numerical techniques. Volume I contains a complete program formulation and Volume III is a users manual.

The development of PADS was conducted by McDonnell Douglas Astronautics Company at Huntington Beach, California, under NASA contract NAS 9-12059, under the cognizance of Mr. Robert Abel, NASA, MSC, Houston, Texas. The key MDAC personnel who formulated and programmed PADS are Messrs. Murray H. Rosenberg, John W. Hensley, and Michael Beach. Valuable programming assistance was given by Larry Ong, Fred Gangloff, and Sheldon Herman.

#### ABSTRACT

The Performance Analysis and Design Synthesis (PADS) computer program has a two-fold purpose. It can size launch vehicles in conjunction with calculus-of-variations optimal trajectories and can also be used as a general-purpose branched trajectory optimization program. In the former use, it has the Space Shuttle Synthesis Program as well as a simplified stage weight module for optimally sizing manned recoverable launch vehicles. For trajectory optimization alone or with sizing, PADS has two trajectory modules. The first trajectory module uses the method of steepest descent; the second employs the method of quasilinearization, which requires a starting solution from the first trajectory module.

# Section 1 INTRODUCTION

The PADS computer program is actually a merger of four separate programs. Each of the separate programs, hereafter called modules, has its own function to perform. Above all of these modules is a main program which calls the appropriate modules into action whenever the problem at hand requires. This main program also controls auxiliary activities concerned mainly with reading in data and communicating data from one module to another. The main modules and auxiliary functions fit naturally into an overlay structure which permits loading this very large program into a moderate core size on either the CDC 6000 or UNIVAC 1108 computer. This overlay structure is illustrated in Section 2 of this volume. The basic modules and auxiliary functions of PADS are listed and defined below.

#### Basic Modules

Overlay	Name	Abbreviation	Purpose
(3, 0)	Steepest Descent	SD or TOPM	Optimize trajectory and staging approximately and provide starting solution for the quasi-linearization module
(4, 0)	Quasi-Linearization	QL or GROPE	Solve Euler-Lagrange boundary value problem (calculus of variations)
(6, 0)	Phase I Sizing	SIZE	Synthesize generalized two- stage launch vehicle (simple sizing)

Overlay	Name	Abbreviation	Purpose
(7, 0)	Space Shuttle Synthesis Program	SSSP	Synthesize two-stage manned recoverable launch vehicle
	Aux	iliary Functions	
(1,0)	INPUT Editor	INEDIT	Read NAMELIST type input and store input data on file for access by various modules
(2,0)	First Input Scan	GEINP	Scan and prepare basic input data for SD and/or QL module execution
(3, 1) -	Second Input Scan	SDINP	Scan boundary conditions and set up steepest descent module data
(5,0) .	Sizing Trajectory	SIZIN	Alter weights and other physical data according to sizing computation in SSSP or SIZE module in prepar- ation for trajectory computation

This volume is organized according to the structure of the program. The next section describes how the main program and auxiliary functions interact with and permit communication between modules. Descriptions of the coding in each module are given in later sections.

The coding documentation includes subroutine glossaries, listings, flow charts, and descriptions of purpose and logic flow. Where possible, subroutine descriptions are tied back to the formulation document.

The documentation of each module consists of the description of the executive program, followed by a set of common glossaries pertinent only to that module. This is followed, in turn, by alphabetically ordered subroutine descriptions.

The final section of this volume contains a discussion of ground rules for modifying the computer program.

# Section 2 OVERALL PADS PROGRAM ORGANIZATION

The main program of PADS is called PADS1. Its flow chart is presented in a figure, with listing and glossary of terms placed directly after. The listings given in this section are flow-listed to indicate transfers within each routine. The listings have been made for the CDC 6500 version of PADS, with some notes where appropriate to indicate differences in the UNIVAC version. A key difference between CDC and UNIVAC listings is that the CDC listing contains a complete picture of all common blocks, whereas the UNIVAC listing only has INCLUDE statements for the common blocks.

Following the PADSI description is a diagram of the PADS overlay structure, and COMMON block glossaries and subroutine descriptions that are shared by different modules.

### Program PADS

### Purpose

Program PADS is a dummy main program used to call the main executive routine, PADS1.

### · Description

The CDC version of PADS defines the required logical units in its argument list. The UNIVAC version has no such requirement.

PADS

PROGRAM PADS(INPUT=1002, OUTPUT=1002, TAPE6=GUTPUT, TAPE5=INPUT, #TAPE1=1002, TAPE12=1002, TAPE4=1002, TAPE10=TAPE12)
CALL PADS1
END PADS AAA PADS PADS

N

# SUBRØUTINE PADS 1

# SUBRØUT INE PADS 1

# SUBRØUT INE PADS 1

#### Subroutine PADS1

### Entry Points SIZERR, SDERR, QLERR

### Purpose

PADSI is the main executive routine for the PADS program.

### Description

As the main executive routine, PADS1 calls in the various modules of the program. These modules, shown in the PADS OVERLAY STRUCTURE, are actually a block of coding headed by an executive routine. The way that PADS1 calls in a module is different in the UNIVAC system than with the CDC software. The CDC software requires calls to the OVERLAY routine to bring in the program module, whereas in the UNIVAC version, simple calls to the appropriate executive routine are used. (See program flow list.) Additional differences in the UNIVAC version of PADS1 exclude the use of blocked binary files\* and the sharing of file buffers. \*\* These aspects are not available or necessary on the UNIVAC machine. In the CDC version the routines OPENMS, READMS, and WRITMS are FORTRAN library routines \*\*\* that set up, read, and write on random access storage. The UNIVAC version of PADS has special versions of these routines that in turn call-UNIVAC-MSC peculiar routines RINIT, RREAD, and RWRITE (random access drum storage and retrieval routines).

The CDC 6000 system of disc storage is entirely logical unit number-oriented whereas random storage on the UNIVAC-MSC system is not. Following is a chart showing how non-core storage is set up on the UNIVAC system.

#### Entry Points

The entry points SIZERR, SDERR, and QLERR are control error returns that are called from various points in the different modules to return control to the proper place in the executive routine (PADS1). Depending on flag setting, corrective action is taken or the next case of input data is requested.

<sup>\*</sup>CDC listing: CALL FTNBIN (1, 3, IBLKN). See CDC Scope 3, 0 manual.

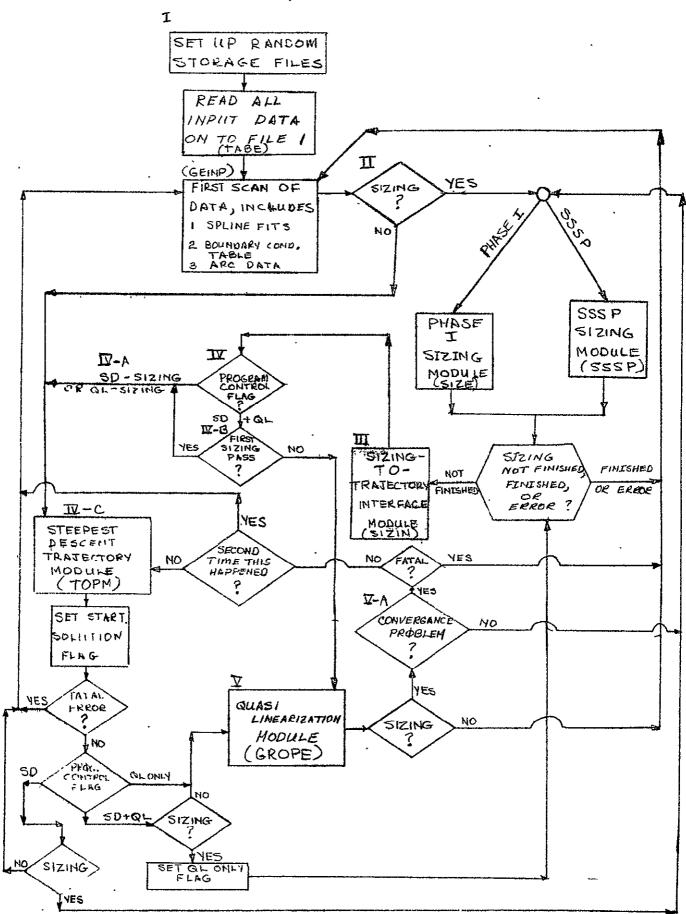

<sup>\*\*</sup>CDC listing: CALL EQUBUFF (5LINPUT, 10, IIN, IFET, IEF)

<sup>\*\*\*\*</sup>CDC FORTRAN Manual

### UNIVAC Logical Unit Descriptions

Internal Logical Unit Number	Purpose	Type	Description
1	Input data file created by INEDIT	FASTRAND	Control card assigned as FASTRAND file 'A'
3	Scratch random file used by INEDIT	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
14	INEDIT scratch and Q-L Scratch	H.S. Drum Sequential	• •
5	INPUT	Card Reader	
6	OUTPUT	Printer	
9	Arc data and boundary conditions	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
10 .	Scratch file used in TRAN3	FASTRAND	Assigned as FASTRAND file 'H'
11	Starting solution file	FASTRAND or Tape	Assigned as File I either tape (to save) or FASTRAND
12	Used in Q-L solution	H.S. Drum sequen- tial	Automatically assigned to first half of drum
33 .	Bivariant aero coefficients set number 6	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
34	Bivariant aero, coefficients set number 7	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
35	Bivariant aero coefficients set number 8	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
<u> 3</u> 6	Bivariant air breather engine data set number 9	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
39	Steepest descent trajectory storage	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
40	Steepest descent trajectory storage	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND
41	Steepest descent adjoint storage	H.S. Drum Random	Automatically assigned to second half of drum to overflow on to FASTRAND

### SUBRØUT I NE I SPRAT

#### Subroutine ISPRAT

#### Entry ISPIN

#### Purpose

Subroutine ISPRAT computes the effective ISP for the dual engine simulation associated with SSP sizing problems.

#### Description

The equations in ISPRAT are described in Section 7 of Vol I. Entry point ISPIN is called to initialize the vacuum thrust values and ISP ratio of the two engines.

# SUBRØUT I NE TABIN

### SUBROUTING TABIN SPECIFICATIONS

#### 1. PESCRIPTION

#### 'urpose:

Inputs a new case of data or inputs data for a different part case of the current case.

#### Comments:

Thus subroutine is to be a library subroutine.

for other information on this subroutine see also the General Programming "mual (AGI) published by MDAC for professional programmers and also bystem Pulletin, Peries 1108-10, dated 28 Oct. 1968.

#### lise:

Calling sequence is CALL TABLE (A, I, D, J, T, k, I, IFC, NUCASE, IEØD) where

- is a one-dimensional array allotted for the storage of alphanumeric information. Blanks will be placed in this array refore the data are input.
- is an integer constant or variable whose value  $(\geq 1)$  is the size of the array A.
- is a one-dimensional array allotted for the storage of Table C data. Peros will be placed in this array before the lata are input.
- is an integer constant or variable whose value  $(\underline{z}, 1)$  is the side of the array 0.
- " is a one-dimensional array illotted for the storage of the table of tables and the table data. Geros will be placed in this array before the data are input.
- is an integer constant or variable whose value (\_ 1) is the size of the array T.
- is a one-dimensional array which contains four locations. The basic deck number will be stored in P(1), the reference run number in M(2), the case number in M(3), and the part case number in P(4). Initially, this array must contain zeros. Once "ABIL has been called, this array must not be changed or zeroed out.
- IPC is an integer constant or variable whose value in the part case number requested.

NUCASE is an integer constant or variable whose value is zero if the current case is to be used, one if a new case is requested.

is an integer variable whose value will be set to plus one if there is no more data, and minus one if the part case requested was not input; otherwise, it is set to zero.

#### input:

TABIN reads tape NTAPE, which is set to equal FORTPAN logical tape 1.

The format of NTAPF is as follows:

Record n. Basic deck number n=1,3,5,...,k Reference run number Case number

Fart case number

Number of words of alphanumeric information

Number of words in Table 0

Humber of words in tables other than Table 0

(including table of tables)

Record n+1, Alphanumeric information

n=1,3,5,...,k Table 0 data

Table data other than Table 0 (including table of tacles)

Record k+2 Basic deck number = 9999

Six additional words, corresponding to the format of record n.

End of file.

#### Error Notes:

"BD = XXX, LR = X4, CAGH = XXX, PC = X4 ALPHANUTERIC ARRAY SIZE TOO SHALL = XX, X4, ILCESSARY SIZE = XXXXX EXECUTION TERMINATED BY TABLE."

"BD = XXX, NR = XX, CASL = XXX, PC = XX ARRAY FOR TABLE O TOO SMALL = XXXXX, REGESSARY SINE = XXXXX EXECUTION TERMINATED BY TABLE."

"BD = XXX, RR = XX, CASE = XXX, PC = XX ARRAY FOR TABLES TOO SMALL = XXXXXI, RECESSARY SIZE = XXXXX EXECUTIO, TERMINATED BY TABLE."

#### Definition of Symbols:

A is a one-dimensional array alloted for the storage of alphanumeric information.

BLAM is a word containing BCD blanks.

11788.27

Is a one-dimensional array allotted for the storage of Table 0 data.

DATA is temporary storage.

is an integer constant or variable whose value is the size of array A.

IBD is the previous basic deck number.

IBD1 is the basic deck number from tape.

113 is the previous case number.

1031 is the case number from tape.

is an integer variable whose value vill be set to +1 if there is no more data, and -1 if the part case requested was not input: otherwise it is set to 0.

IPC is the part case number requested.

IPCl is the part case number from tape.

1RR is the previous reference run number.

IRM is the reference run number from tape.

d is an integer variable whose value is the size of array D.

K is an integer variable whose value is the size of array ".

is used as in index.

is a one-dimensional array which contains four locations. The basic dock number is in M(1), the reference run number is in M(2), the case number is in M(3), and the part case number is in M(4).

WALPHA is the number of words of alphanumeric information.

is the number of words in tables other than Table 0 (including table of tables).

NTABO is the number of words in Table O.

MMAP: is the tape from which data are read.

ARCAGE is 0 if the current case is to be used, I if a new case is requested.

" is a one-dimensional array allotted for the storage of the table of tables and the table data.

# SUBRØUT I NE WTDRP

### Subroutine WTDRP

### Purpose

Subroutine WTDRP calculates the weight dropped at booster staging in the rubber-stage optimization problem. It also calculates the sensitivities of the weight drop with respect to the booster burn-out weight.

### Description

The equations for this routine are described in Section 13 of Volume I.

# SUBRØUT I NE I NED I T

#### Subroutine INEDIT

### Purpose

INEDIT reads input data card images using NAMELIST and stores cases and part cases on input file 1 for access by the various modules of PADS.

#### Description

INEDIT first reads each data card separately, prints its image, and then copies it on to File 4. File 4 will then contain all data card images, and serve as the input file for subsequent NAMELIST reads.

The first NAMELIST read (\$XX) either reads in control flags or fills common block /AA/ with trajectory and Phase I sizing data.

At the end of common block /AA/ are three arrays used for storing the data from the other NAMELIST reads associated with SSSP sizing problems.

These NAMELIST sets are \$DATA 3 and \$DATA 2.

After reading data into common block/AA, INEDIT scans for key quantities that have actually been input (words that are non-negative zero) and sets up part cases to be stored on file 1.

The part case and table structure resulting from this processing are charted below.

| Part<br>Case<br>No. | Description of Data                                            | Common block/ or (routine) where date used | Extent<br>In<br>/AA/ array |
|---------------------|----------------------------------------------------------------|--------------------------------------------|----------------------------|
| 1                   | fixed length table Tables 1-30 variable length univariant data | /GLOBAL/<br>/TBLE/<br>(SPLICO)             | GR → DUM 5<br>CLA (70, 30) |
| 2                   | Table 1 Initial conditions Table 2 Target condition            | (ĠEINP)<br>(BNDRYC)                        | T1-TIME1 PAYOFF-CT20       |

| Part<br>Case<br>No. | Description of Data                                                 | Common block/ or (routine) where date used | Extent<br>In<br>AA array       |  |
|---------------------|---------------------------------------------------------------------|--------------------------------------------|--------------------------------|--|
| 4                   | Table 1, steepest descent starting solution phase sequencing        | (SDIN-P)                                   | PH1→PH20                       |  |

### Subroutine PACKER

### Purpose

Subroutine PACKER packs univariant and bivariate tables for inclusion on file 1.

### Description

PACKER is called by INEDIT to process the input data tables into a form that is stored on file 1.

# SUBRØUT I NE GE I NP

#### GEINP

### Purpose

GEINP reads various data sets from the input tape file, puts some in common blocks, and calls other routines that process data before storing.

#### Description

GEINP is an overlay program on CDC equipment whereas it is a subroutine on the UNIVAC system.

The data that GEINP uses is fetched by calling TABIN according to "Part Case" number. (TABIN reads the data from unit 1. For a description of how data gets on unit 1 see Subroutine INEDIT). The part cases that are read in this routine (in the same order as read) are:

| Part Case<br>Number | Description                                                                                                                            | Common<br>Blocks   |
|---------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------|
| 1                   | GLOBAL, data and univariant tables (subroutine SPLICØ spline fits tables and stores them in common block/TABLE/).                      | /GLOBAL/<br>/TBLE/ |
| 11 - 30             | BLOCKS OF ARC DATA read in and processed by FXDAT and then stored on random file 9, records 1 through 20.                              | /ARCDAT/           |
| 6, 7, 8             | Bivariate aerodynamics tables read in and processed by subroutine BLIC $\phi$ and stored on random files 33, 34, and 35, respectively. | /BICUBE/           |
| 9                   | Bivariate Airbreather thrust table, read in and processed by subroutine BLIC $\phi$ and stored on random file 36.                      | /BICUBE/           |
| 10 .                | SIZING Data is read in and stored in /SIZING/                                                                                          | /SIZING/           |
| 2                   | Boundary condition data is read in and processed in BNDRYC.                                                                            |                    |
|                     | It is stored after processing on random file 9, record 21.                                                                             |                    |

# SUBRØUTINE BLICØ

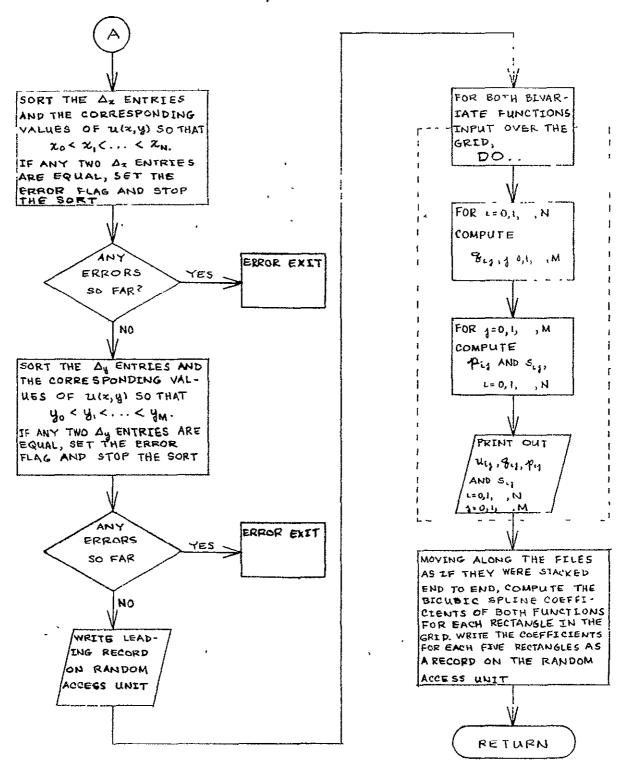

### Subroutine BLICØ

### Purpose

Subroutine BLIC $\phi$  computes bicube spline coefficients and stores them on disc or drum random files.

### BLICO (continued)

| ORIGAN | MAIH           | roce | DESCRIPTION                                                                                           | STORAL    |      |                                                                                                 |                           | USAGE                                                              |

# SUBRØUT I NE BNDRYC

#### Subroutine BNDRYC

## Purpose

This subroutine packs boundary condition data (both initial and target input data) into an ordered packed array which will be stored in a random access file.

## Description

The input to this routine is the array ARR which is an unordered packed representation of the input initial and target conditions. The main function of the routine is to sort the unordered data into a matrix array, concurrently counting the numbers of initial and target conditions in each arc. The number of initial and target conditions is stored by the calling program (GEINP) in arrays ITAB and KTAB respectively.

SUBROUTINE BNDRYC(ARR, ILOC, ITAB, BNARR, N, IEND, IFATAL)

ARR IS THE INPUT ARRAY CONTAINING BNDRY COND. INPUT
LOC IS THE INDEX OF ARRAY IRR WHERE THE BNDRY COND. INPUT START
ITAB IS THE ARRAY WHOSE VALUES ARE THE ADRBER OF INITIAL
CONDITIONS SPECIFIED IN EACH ARC
BNARR IS AN ARRAY CONTAINING IC VALUES AND CLASSIFICATIONS
FOR EXAMPLE CLASSIFICATION CODES ARE*

0. CONTINUOUS
1. KNOWN
2. OPTIMIZED
3. ESTIMATED
4. UNKNOWN
5. DISCONTINUITY IN MASS (WEIGHT)
6. WEIGHT DISCONTIUTY COMPUTED IN WIDROP

#### TOPM

## Purpose

TOPM is the Steepest Descent module main executive program.

## Description

The reader is referred to Section 2.0 of Volume II for a chart of the overlay structure particularly under this routine (TOPM). The chart shows the names of the routines that are called on UNIVAC equipment instead of the overlay numbers used on CDC equipment. A further description of the iteration procedure generated by TOPM is contained in Section 15.3 of Volume I.

## SUBRØUT I NE ACCEL

#### Subroutine ACCEL

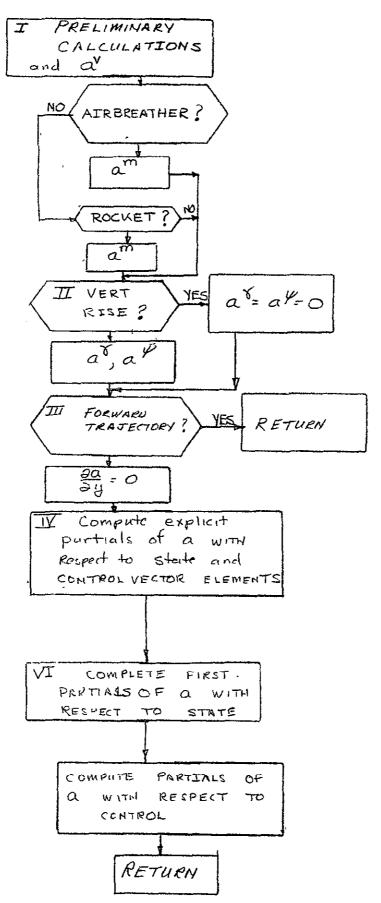

### Purpose

Computes acceleration vector, a, and its partials with respect to state and elements of the control vector. It also computes the complete first partials of the acceleration vector with respect to the state. See Section 9.3 of Volume I.

### Description

During forward trajectory,  $a^V$ ,  $a^V$ ,  $a^{\Psi}$  and  $a^{m}$  are computed. On the adjoint solution, matrix  $\frac{\partial a}{\partial y}$  is also computed. The acceleration vector a is defined in equation (2.4-2) of Volume I.

# SUBRØUTINE ADEQ3A

#### Subroutine ADEQ3A

### Entry Point, ADEQ

#### Purpose

ADEQ3A computes the derivatives of the adjoint differential equations as expressed in equations (12.3-3) through (12.3-8) in Volume I. It also supplies the integrands of the upper triangular portion of the A matrix as given in equation (12.1-20). These, of course, contain functions of the impulse response function as defined in equation (11.1-16).

## Description

This routine is called from BNTG.

# SUBRØUTINE ADICB3

#### Subroutine ADICB3

### Purpose

This subroutine performs calculations of adjoint discontinuities and initializations for branched and intermediate constraint problems. It contains 3 entry points, ADI3B, ADICB, and ADI2B. These entry points are explained below with cross reference to equations in Volume I and Roman numeral comments in the subroutine listing.

#### Description

- I Branch point approached from Branch 3. (Entry ADI3B)
- I-A Save A matrix at this corner point to permit restoration of complete matrix on trunk.
- I-B Reset time and state to end of branch. This will permit initiation of adjoint integration from end of branch 2.
- II Adjoint initial conditions are calculated to initiate Branch 2 and integration. The equation for the adjoint initial condition is (11 5-2).
- . IV At intermediate arc constraint (ENTRY ADICB)

  This entry point sets up necessary data for initializing adjoints at end of intermediate constraint arc. Logic then proceeds to II and III where the initialization equation corresponding to (11.4-3) is computed.

The entry point in this routine is called from BNTG.

## SUBRØUTINE ADIC3A

#### Subroutine ADIC3A

#### Purpose

Subroutine ADIC3A (entry point ADIC) computes adjoint initial conditions at the terminus of the trajectory. After zeroing out the adjoint variable matrix, the impulse response functions and the adjoint integration array (VARL and PVARL), equation (11.1-23) of Volume I is solved.

#### Description

This routine is called from TEST.

| ORTHAN | MATH   | 1006 | DESCRIPTION                                                                     | STORAGE    |      |                                                                                        |                                                |                                                                                        |

## SUBRØUTINE ADID3A

#### Subroutine ADID3A

#### Purpose

Subroutine ADID3A computes adjoint discontinuities for different situations using different entry points. It accounts for branching and intermediate constraints as well as most mixed boundary conditions. Mixed boundary condition adjoint discontinuities are handled for elapsed time and functions of elapsed time only.

#### Description

Preliminary calculations at each entry point use the local range of the  $d\psi$  vector to determine which adjoint sets are to be considered.

It should be noted that this subroutine is not called if the cut-off function is on fixed arc time. This routine's entry points are called from BNTG.

# SUBRØUT I NE ADJUST

#### Subroutine ADJUST

#### Purpose

Subroutine ADJUST has several entry points; each is described below.

#### Description

Entry ADJUS. This entry adjusts initial states that are to be optimized. It will also set the arc time optimization flag, ITI, if the first arc time duration is to be optimized. After computing the adjustable parameter increment in MTX1, the free initial state is adjusted and the sensitivity is removed from the sensitivity matrix. The number of free parameters is also reduced appropriately.

Entry ADJIN. This entry checks for arc time duration optimization in the prior arc. If it occurs, the logic eliminates the appropriate elements in the sensitivity matrix and reduces the number of free parameters by one.

The entry points in this routine are called by FNTG.

Entry ADJUT. This entry adjusts the free arc time cut-off value using the currently computed value of the parameter correction. It also forces a concurrent phase-time cut-off to occur at the same time as the arc-time cut-off.

# SUBRØUTINE AGETB3

#### Subroutine AGETB3

#### Purpose

Fetches state and control from random access file for use in adjoint solution.

#### Description

This routine has two entry points.

Entry BEGNA: This entry initializes reading the forward trajectory at final trajectory time. This initialization involves determining the last buffer number that was written into and how many words were written there. Starting from there the program may proceed backwards to extract data at monotonically decreasing time points to correspond exactly with the adjoint integration time points. BEGNA is called from BNTG.

Entry AGETB: This entry simply steps backward in the buffer array and loads the trajectory data into the appropriate common locations. When the starting location of the buffer is reached, the next lower buffer is loaded in from the random file and the process of backward data extraction starts over. AGETB is called from MODELB.

# SUBRØUT I NE AST3

#### Subroutine AST3

#### Purpose

This routine handles both storage and retrieval of trajectory data during forward trajectory integration. Each entry point is defined herein.

#### Description

Entry BEGWR: Initializes counters for storage of trajectory on random file. BEGWR is called from FNTG.

Entry ENDWR: Saves values of counters after trajectory has been stored and "dumps" last partial buffer on random file. ENDWR is called from FNTG.

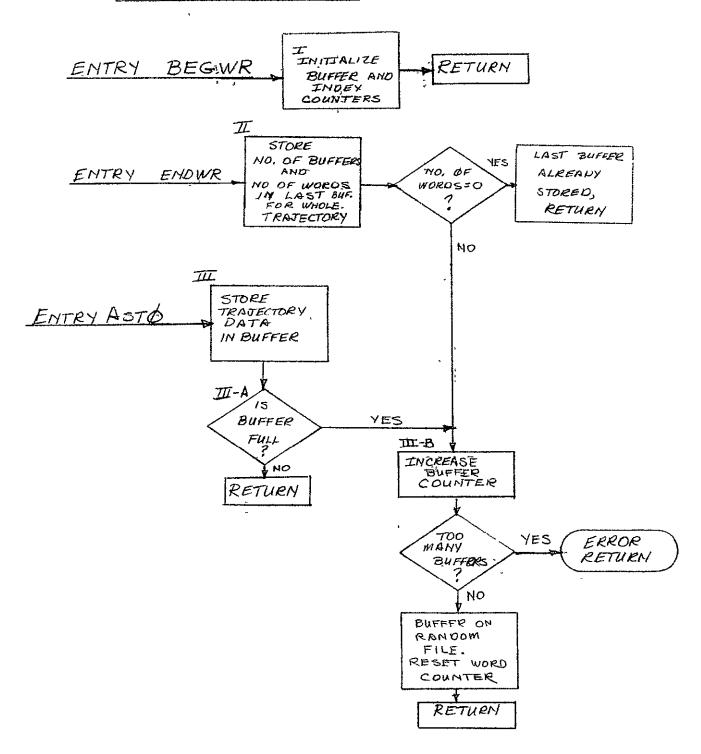

Entry AST $\phi$ : Stores trajectory data in buffer and when buffer is full "dumps" buffer on random file. AST $\phi$  is called from entry CORVAR in REU3 and also FNTG.

Entry BGRA: Initializes read of trajectory data.

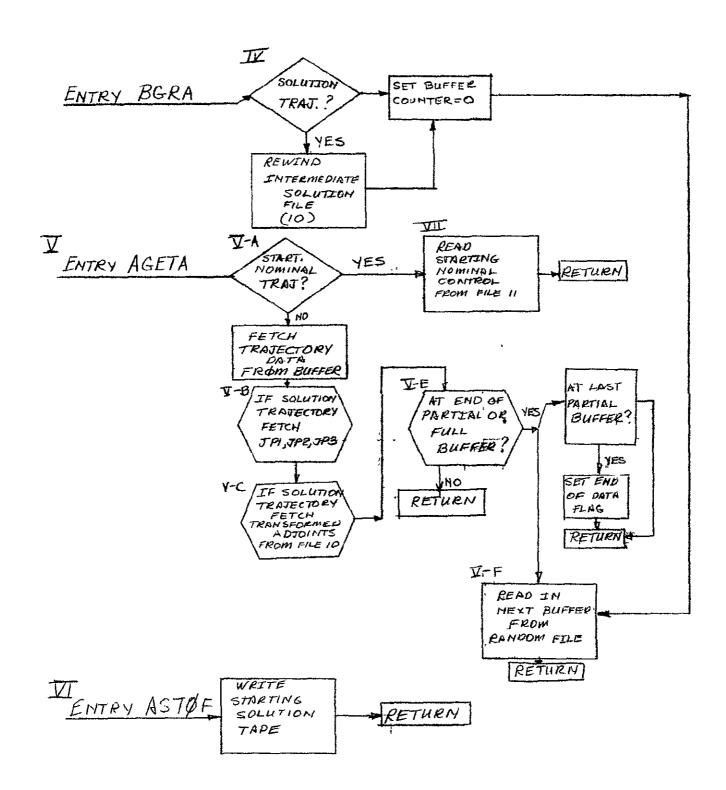

Entry AGETA: Reads data from storage buffer, or if on a starting trajectory, reads data from starting solution file 11. AGETA is called from MODELA.

Entry AST $\phi$ F Writes starting solution on file 11. ASTOF is called from FNTG.

# SUBRØUT I NE BERØCØ

#### Subroutine BERØCØ

### Purpose

Computes total aerodynamic coefficients for all aerodynamic options. Also computes partials of coefficients with respect to state and control.

### Description

BER $\phi$ C $\phi$  is called from subroutine VT.

# SUBRØUT I NE BGET3

#### Subroutine BGET3

#### Purpose

This subroutine retrieves all adjoint data during forward trajectory. It has an initialization entry point called BGRB and a main entry point, BGET.

#### Description

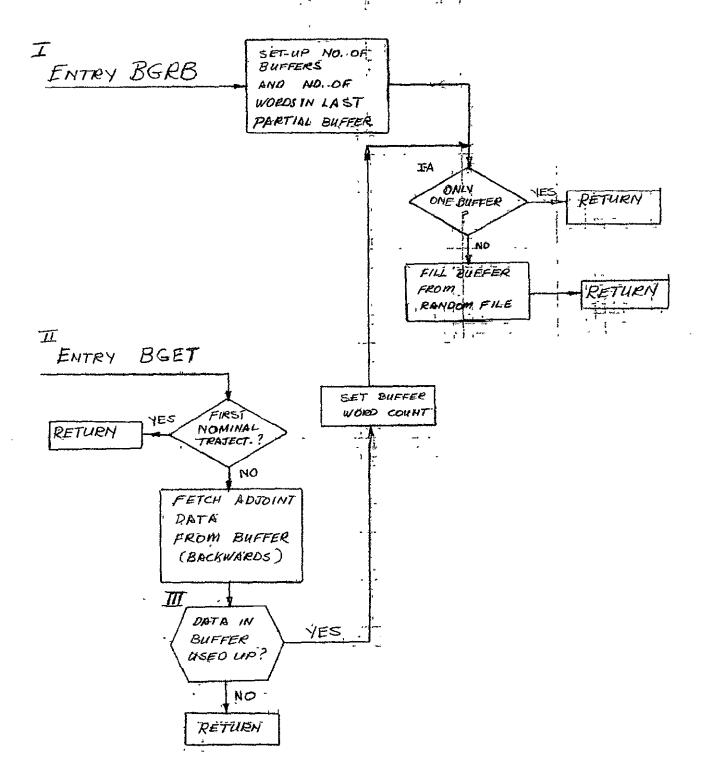

Entries BGRB and BGET are called from various routines in the module.

BGET and BGRB are called from FNTG.

BGET is called from GETIT.

BGRB and BGET are called from TRAN3.

### SUBROUTINE BEET3.

### SUBRØUTINE BLGCØN

#### Subroutine BLGCØN

#### Purpose

Subroutine BLGC $\emptyset$ N solves for the in-plane control vector, w, and also during the adjoint solution computes the explicit and complete partials of the control vector with respect to state and control. The method of solution for the in-plane control vector is described in Section 9.2 of Volume I. The detailed logic flow description of this subroutine may be found in subroutine ALGC $\emptyset$ N which is the Quasi-linearization module version of BLGC $\emptyset$ N.

#### Description

BLGCØN is called both during the forward trajectory by subroutine MODELA and during the adjoint solution by subroutine MODELB.

#### Subroutines BL2 Through BL9

#### Purpose

Subsoutine BL2 through BL9 supply (on option) the governing equation for the angle of attack,  $\alpha$ , element of the in-plane control vector. This is governing equation  $K_3$  described in Sections 9.2 and 10 of Volume I. The correspondence between subroutine and steering options is listed below:

| Subroutine Name | Steering Control Option                                    |
|-----------------|------------------------------------------------------------|
| BL2             | Constant angle of attack                                   |
| BL3             | Constant lift                                              |
| BL4             | Vertical rise of pitchover, $\mathring{\gamma}_{\neq}^* 0$ |
| BL5             | Unpowered total acceleration limit                         |
| BL6             | Gravity turn                                               |
| BL7             | Dynamic pressure limit                                     |
| BL8             | Heating rate limit                                         |
| BL9             | Reynolds number limit                                      |

Subroutines BL2 through BL9 are simplified versions of AL2 through AL9 used in the quasi-linearization module of PADS.

Each routine has a hierarchy of entry points. The entry points for example in BL7 include BL7010, BL7001 and BL 7000. The meaning of the numbers is similar in all of the "BL" routines and is spelled out below. (Subroutine BL7 is used only as an example).

Entry BL7000. Computes value of K3, the governing equation.

Entry BL7001. First computes partials of  $K_3$ , with respect to elements of the in-plane control vector and then computes  $K_3$ .

Entry BL7010. Computes explicit partials of  $K_3$  with respect to state, then computes partials of  $K_3$  with respect to the in-plane control vector and finally computes  $K_3$ .

### SUBRØUT I NE BNTG

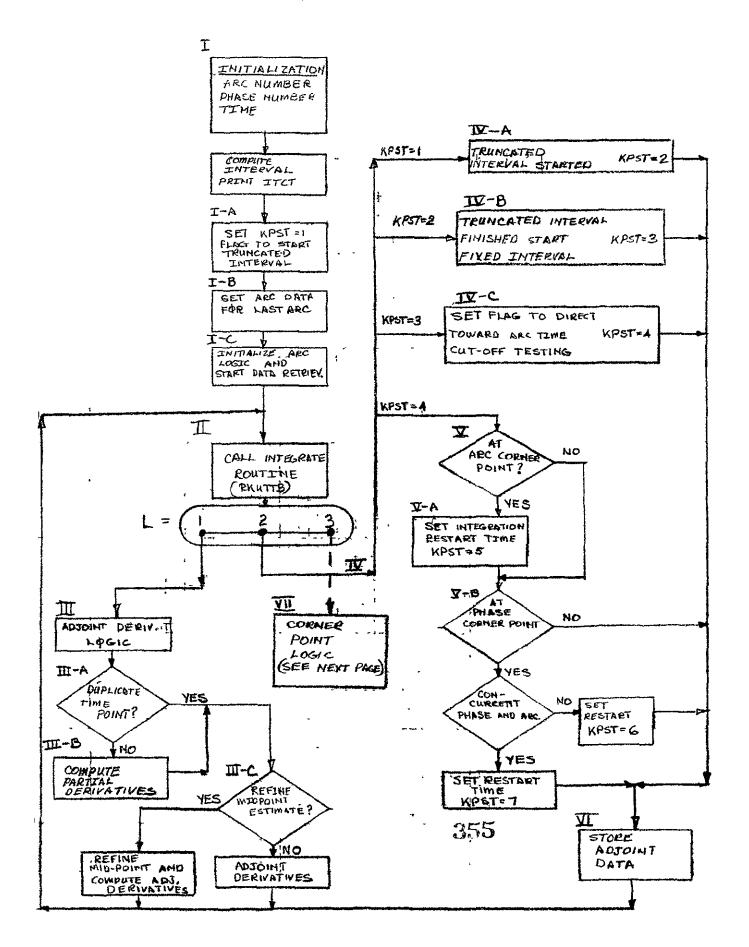

#### BNTG

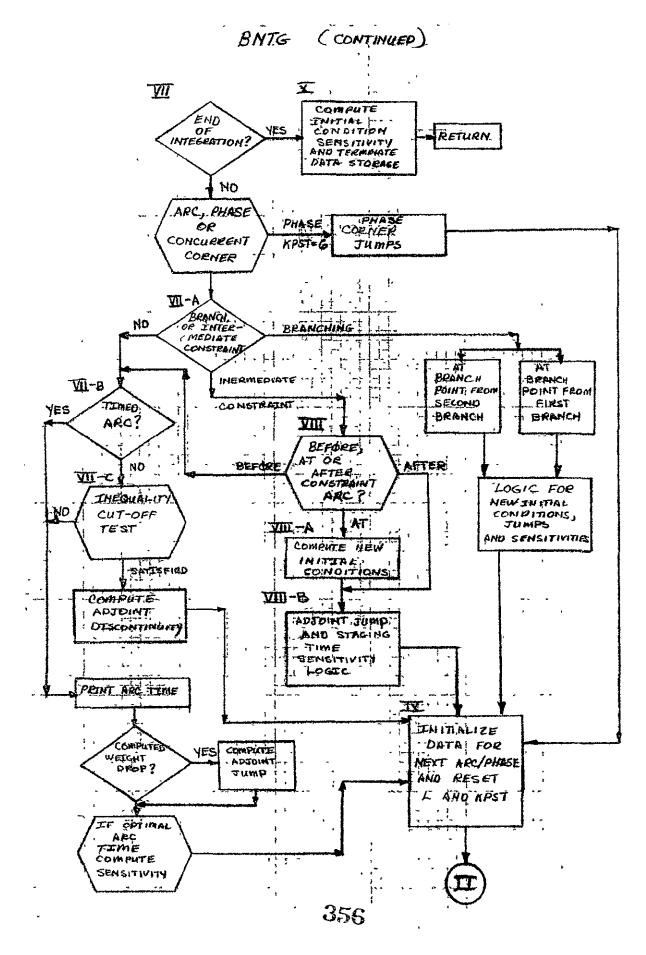

#### Purpose

BNTG is an executive routine that controls integration of adjoint system. On the CDC computer overlay software, it is a program that heads up an overlay, whereas on the UNIVAC system it is a subroutine.

#### Description

The key aspect of the backward adjoint integration logic is that the compute intervals are precisely matched to the previous nominal forward trajectory compute intervals. The integration is started at the end of each arc using a saved truncated time interval (the same truncated interval required to satisfy the arc cut-off on the nominal trajectory). After completing the interval, the integration is restarted with the full step size and continues until the beginning of the arc. This process continues until the beginning of the first arc where the logic recognizes (VII) that initial time has been reached and proceeds to terminate storage of adjoint data (X).

# SUBRØUT I NE BSTØ3

#### Subroutine BST03

### Purpose

BST03 handles the storage of the adjoint data first in a dynamic buffer, Z, and when this buffer is filled, it dumps the buffer onto random storage file 41.

This subroutine also has an entry point SNSADJ which refines the impulse response function,  $\Lambda^{\Psi_i\;\Omega_j}$ , estimate at mid-integration interval before storing.

### Description

The order of storage of information at each adjoint-solution time point in the Z buffer is listed below.

- 1. The adjoint variable  $\lambda^{\Psi_1\Omega_j}$  matrix is stored. Each column in this matrix corresponds to a different constraint,  $\Psi_1$ ; each row corresponds to an element in the state vector.
- 2. The impulse response function vectors are stored. These vectors, XLAMA and XLAMP contain an element for each element in the  $d\Psi_1$  vector.
- 3. The upper triangular portion of the A matrix is stored.—Only this part is needed since A is a symmetric matrix.

# SUBRØUT I NE CØN3

#### Subroutine CON3

### Purpose

Subroutine CON3 computes the constraint misses and payoff. It has two entry points the first, CONIN, sets up and computes constraint misses, ACON, for the first nominal trajectory; whereas the entry CON computes trial constraint misses and payoff, BCØN. These trial constraint misses later become nominal values in subroutine TEST if the trial trajectory is acceptable.

#### Description

The main logic in this subroutine is governed first by the argument list (MM, MN) which indicates partitioning of the  $d\psi_i$  vector and second by the constraint variable code pointer ITQ.

MM is the first element in  $d\psi$ , to be evaluated and NN is the last.

The ITQ pointers tell whether the constraint or payoff is elapsed timed, an element of the state vector or a non-linear constraint.

# SUBRØUT I NE DER3A

#### Subroutine DER3A

## Entry Points DER

### Purpose

Subroutine DER3A computes the derivatives of the equations of motion for the forward steepest descent trajectory.

#### Description

The equations programmed in subroutine DER3A are given in Volume I, Section 2.3. The acceleration vector component AV, AG, AP and AM are computed in subroutine ACCEL.

# SUBRØUT I NE DTF3

#### Subroutine DTF3

## Entry Point, DTF

### Purpose

Subroutine DTF3 computes integration interval to approximately hit a state or function cut-off.

### Description

After the forward integration controlling subprogram, FNTG, detects that an arc cut-off is imminent, DTF3 is called to estimate the integration interval to satisfy the cut-off function. This is done using the equations described in Volume I, Section 15.2, equations 15.2-3 through 15.2-11.

# SUBRØUT I NE EL 1

#### Subroutine EL1

## Entry EL1001, EL1000

## Purpose

Subroutine EL1 is a governing equation for the computation of the engine, deflection component of the in-plane control vector. It corresponds to fixed engine deflection.

## Description

The in-plane control vector computation is described in Volume I, Section 9.

# SUBRØUT I NE EL2

#### Subroutine EL2

Entry Points. EL2010, EL2001, EL2000

#### Purpose

Subroutine EL2 is a governing equation for the computation of the engine deflection component of the in-plane control vector.

It corresponds to variable engine deflection to balance all or part of the aerodynamic moment.

#### Description

The governing equation, XK2, computed in EL2, represents the balance of the aerodynamic moment given in Volume I, equation 3.1-12 by the engine moment as given in 3.1-17. The complete description of the in-plane control vector calculation is given in Section 9 of Volume I. The entry points, are used for separating the calculation of partials derivatives of XK2 with respect to in-plane control vector elements and with respect to the state vector.

## SUBRØUT I NE ENVPRM

#### Subroutine ENVPRM

#### Entry Points. ENVPRI

#### Purpose

ENVPRM computes steepest-descent-solution trajectory environmental parameters that affect vehicle weight. It is used with SSSP sizing synthesis problems only.

#### Description

Subroutine ENVPRM is called by MODELA at every compute interval of the steepest descent solution trajectory on SSSP type sizing problems.

On branched trajectories having an atmospheric entry portion, it computes maximum dynamic pressure times angle of attack product  $(q\alpha)$ , threshold heat load, and maximum total load factor.

During boost, it computes maximum dynamic pressure and also saves the velocity, altitude flight path angle, time, and Mach number at the point where the maximum dynamic pressure occurs.

Entry point ENVPRI initializes the threshold heat load to zero at the beginning of the trajectory.

## SUBRØUT I NE EQUA3

#### Subroutine EQUA3

### Entry Point. EQUA

#### Purpose

Subroutine EQUA3 computes functions of state only during the integration of the forward steepest descent trajectory and also during the adjoint integration.

#### Description

The basic logic of this subroutine depends first of all on whether a vacuum simulation, IATM=3, is desired and second whether a forward or adjoint integration is in progress. Secondary logic accounts for the types of table look-ups that are required according to simulation options.

# SUBRØUT INE FH1

#### Subroutine FM1

Entry Points. FH1001, FH1000

#### Purpose

Subroutine FH1 is the governing equation (XK1) associated with the thrust element in the in-plane control vector when the thrust is a constant.

### Description

The solution of the in-plane control using the governing equations is described in Section 9 of Volume I. This subroutine is called from BLGCØN.

# SUBRØUT I NE FH2

#### Subroutine FH2

Entry Points. FH2010, FH2001, FM2000

#### Purpose

Subroutine FH2 is the governing equation (XK1) associated with the thrust element in the in-plane control vector when the thrust is modeled as a vacuum thrust modified by a nozzle back-pressure correction.

#### Description

The solution of the in-plane control using the governing equations is described in Section 9 of Volume I. This subroutine is called from BLGCØN.

# SUBRØUTINE FH3

### Subroutine FH3

# Entry Point. FH3010, FH3001, FH3000

### Purpose

Subroutine FH3 is the governing equation (XK1) associated with the thrust element in the in-plane control vector when the thrust is being throttled to maintain a limit total acceleration.

# Description

The solution of the in-plane control using the governing equations is described in Section 9 of Volume I. This subroutine is called from BLGC $\emptyset$ N.

# SUBRØUT I NE FH4

### Subroutine FH4

# Entry Points. FH4010, FH4001, FH4000

## Purpose

Subroutine FH4 is the governing equation (XK1) associated with the thrust element in the in-plane control vector when the airbreathing propulsion option is used.

## Description

The solution of the in-plane control is described in Section 9 of Volume I. This subroutine is called from BLGC $\phi$ N.

# SUBRØUT I NE FNTG

#### FNTG

# Purpose

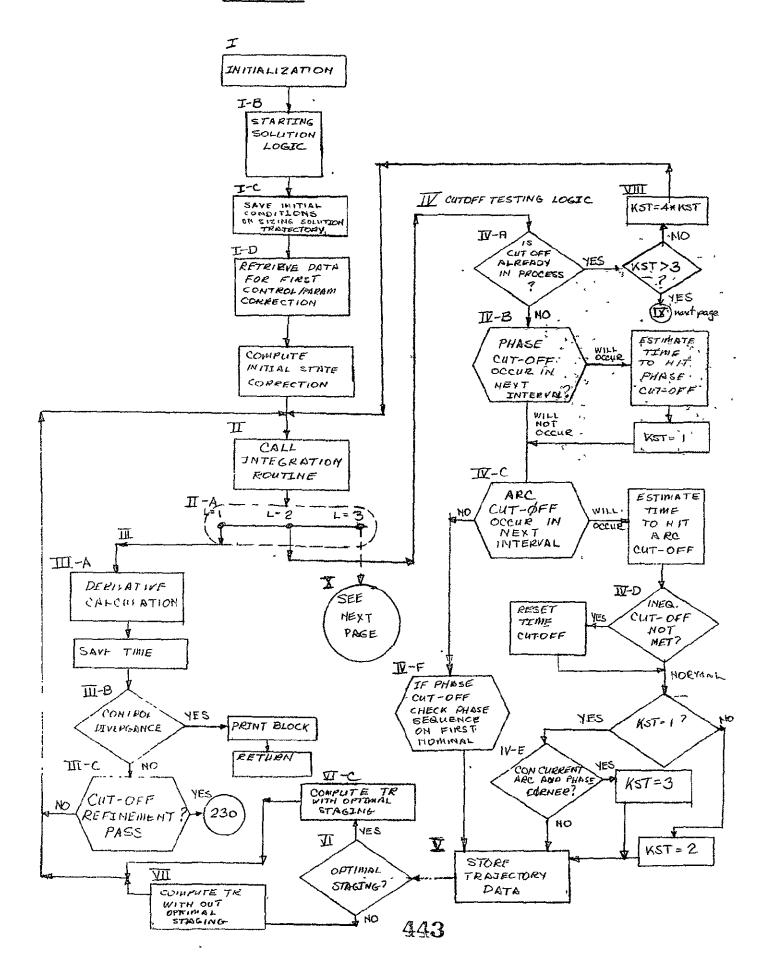

FNTG controls integration of forward trajectory and all subsidiary functions.

### Description

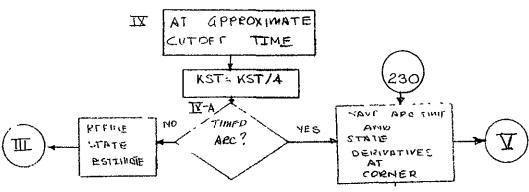

FNTG is a subroutine in the UNIVAC version of the program, however, in the CDC version of PADS it is a "Program" which heads up the largest overlay in the steepest descent module.

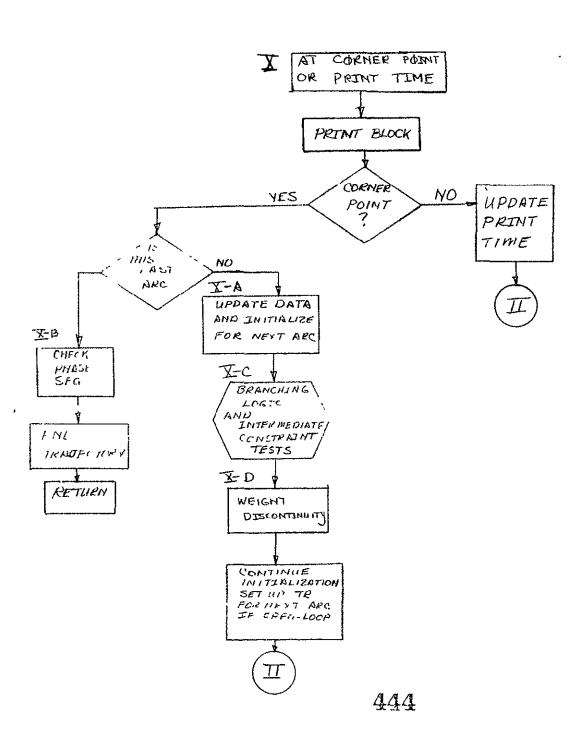

The logic in this program is geared mainly to the Runge-Kutta numerical integration subroutine, RKUTTA. Through the use of the traffic flag, L. The meanings of L are listed below.

- L = 1, Evaluate derivatives
- L = 2, Check cut-off and store data
- L = 3, At corner point or print time
- L 4, Restart integration.
